Memo – shortage of supply

To: Clinical Teams
From: Medicines Information
Date: 9/2/2016

Re: Cyclizine lactate 50 mg/ml Injection

Description of product affected

Cyclizine is licensed for the prevention and treatment of nausea and vomiting in adults including:

- Motion sickness when the oral route cannot be used.
- Nausea and vomiting caused by narcotic analgesics and by general anaesthetics in the post-operative period.
- Vomiting associated with radiotherapy especially for breast cancer since cyclizine does not elevate prolactin levels.
- Pre-operative use in patients undergoing emergency surgery in order to reduce the hazard of regurgitation and aspiration of gastric contents during induction of general anaesthesia.

The SPC also mentions that cyclizine may be of value in relieving vomiting and attacks of vertigo associated with Menière's disease and other forms of vestibular disturbance when the oral route cannot be used. The injection is administered by the intramuscular or intravenous route up to three times daily.¹

Background

There is a delay to the delivery of cyclizine injection and stock is now expected in mid-March 2016. LTHT currently hold stock which will last for approximately 2 weeks at normal usage levels.

Current usage

- There is a well defined role for cyclizine injection in the palliative care setting. ³⁴ Because of its antimuscarinic properties, the use of cyclizine tends to be restricted to situations where metoclopramide and/ or other more specific antiemetics (e.g. haloperidol, 5HT3 antagonists) have failed to provide relief e.g. some patients with mechanical bowel obstruction or as the antiemetic of choice for raised intracranial pressure. In the UK, cyclizine is generally the antihistaminic antimuscarinic anti-emetic of choice.⁵
- Cyclizine is commonly used for the prevention and management of postoperative nausea and vomiting.
- Cyclizine can be administered by midwives in the course of their professional practice under the Medicines Act exemptions i.e. without the need for a prescription from an authorised prescriber or without the need for a specific Patient Group Direction.⁶⁷
Alternative agents and management options

Drugs used for postoperative nausea and vomiting include 5HT\textsubscript{3}-receptor antagonist, some phenothiazines, and antihistamines. A combination of two or more antiemetic drugs that have different mechanisms of action is often indicated in those at high risk of postoperative nausea and vomiting (PONV) or where postoperative vomiting presents a particular danger (e.g. in some types of surgery). When a prophylactic antiemetic drug has failed, PONV is treated with one or more drugs from a different class. Other antipsychotic drugs including haloperidol and levomepromazine are used for the relief of nausea and vomiting in terminal illness.\textsuperscript{8}

The only other antiemetic midwives can administer under the Medicines Act exemptions is prochlorperazine injection.\textsuperscript{6} Alternative agents would be ondansetron or metoclopramide injection but a prescription would be required. In practice, ondansetron would be used postnataally and not during delivery. Metoclopramide is usually avoided in this patient group as some may not tolerate it. However there may be more experience in this area with use of the latter agent.\textsuperscript{7}

Due to the large cost increase in cyclizine, there has been a move in some areas towards use of ondansetron, but there may be a small number of patients who will need cyclizine if other antiemetics are unsuitable or ineffective\textsuperscript{5} as it tends to have fewer interactions with other medications or additive side effects.\textsuperscript{3}

In order to preserve existing stock for critical areas, cyclizine may need to be restricted for palliative care use and no longer used as a first line antiemetic in areas where alternatives antiemetics are available, such as using ondansetron for post operative N\&V. Advice should be sought from the relevant specialist team in the event of a shortage. Importers are currently investigating availability of cyclizine from outside the UK.

The table below outlines some of the treatment alternatives:
